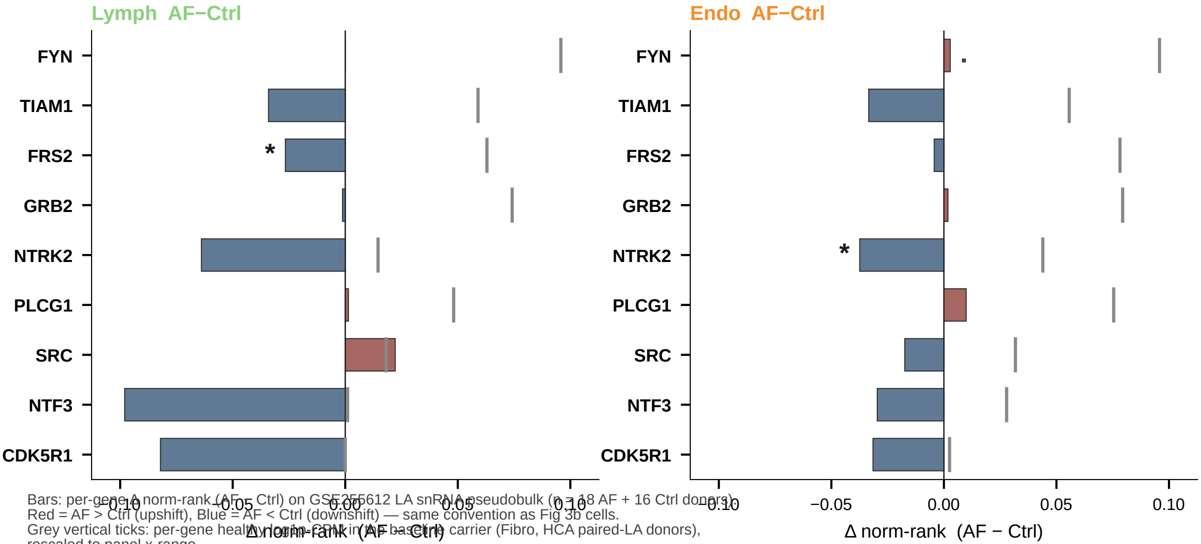
Fig 3d F15 NTRK2 / TrkB — Cellular relay

Cellular relay



Bars: per-gene Δ norm-rank (AF − Ctrl) on GSE255612 LA snRNA pseudobulk (n = 18 AF + 16 Ctrl donors). Red = AF > Ctrl (upshift), Blue = AF < Ctrl (downshift) — same convention as Fig 3b cells. Grey vertical ticks: per-gene healthy log1p-CPM in the baseline carrier (Fibro, HCA paired-LA donors), rescaled to panel x-range.

Bars in non-carrier compartments (lymphocyte, endothelial) reveal a predominantly AF-time downshift. The bulk-detected attenuation (Fig 2C, F15 = Att 2/3) therefore originates from cellular relay rather than carrier-intrinsic change. Note that the relay is NOT a uniform downshift of every LE gene: SRC (in lymphocyte) and PLCG1 (in endothelial) show modest upward drift, indicating compartment-specific divergence within the same pathway.

Significance markers: * = gene-level $p < 0.05$; . = gene-level $p < 0.10$ (donor permutation, n_perm = 5000). Color note: cellular-fidelity badge colors (purple = relay, teal = extension) are decoupled from the carrier palette in Fig 3b to avoid cross-figure confusion.
